## **Quiz 5 Solutions**

This quiz will give you practice on group by statements and aggregate functions when grouping by a single column. For this quiz please use the data from here:

bigquery-public-data.new\_york\_trees.tree\_census\_2015

Read over the schema page as it will explain what each column in the dataset means.

1.

When counting the number of trees by health, which group within health has the least amount of trees?

Which has the most? Note: Null can be an answer.

```
SELECT health, COUNT(DISTINCT tree_id) as num_trees

FROM `bigquery-public-data.new_york_trees.tree_census_2015`

GROUP BY health ORDER BY num_trees desc
```

2.

For each type of tree (use the spc\_common column), calculate the average diameter (use the tree\_dbh column).

How many types of trees have an average diameter strictly greater than 10?

```
SELECT spc_common, AVG(tree_dbh) AS avg_tree_diameter
FROM `bigquery-public-data.new_york_trees.tree_census_2015`
GROUP BY spc_common HAVING avg_tree_diameter > 10
ORDER BY avg_tree_diameter DESC
```

3.

Of all the trees that have a health status of "Poor" and a tree diameter greater than 10 (tree\_dbh > 10), how many are Damaged and how many are Not Damaged (as measured by the sidewalk column)?

```
SELECT sidewalk, COUNT(DISTINCT tree_id) AS num_trees

FROM `bigquery-public-data.new_york_trees.tree_census_2015`

WHERE health = 'Poor' AND tree_dbh > 10

GROUP BY sidewalk
```

4.

Consider the trees for which user\_type is "TreesCount Staff" or "NYC Parks Staff", and spc\_common is not "London planetree", and curb\_loc is "OffsetFromCurb". For the trees that meet these conditions, find the maximum tree\_dbh for each of the different categories/groups in the guards column.

```
SELECT guards, MAX(tree_dbh) AS max_tree_diameter

FROM `bigquery-public-data.new_york_trees.tree_census_2015`

WHERE user_type IN ("TreesCount Staff", "NYC Parks Staff")

AND spc_common != "London planetree"

AND curb_loc = "OffsetFromCurb"

GROUP BY guards
```

5.

What is the maximum, minimum, and average tree\_dbh across the entire data set?

HINT: When using aggregate functions, you do not have to use a group by. You can just use aggregate functions in a simple select statement from the table. It will work as long as you are only returning aggregated columns and not ordering by any column.

For example (although this is rather meaningless) it will still execute:

```
SELECT

SUM(tree_dbh)

FROM

`bigquery-public-data.new_york_trees.tree_census_2015`
```

SELECT MAX(tree\_dbh) AS maximum\_tree\_dbh,

MIN(tree\_dbh) AS minimum\_tree\_dbh,

ROUND(AVG(tree\_dbh),2) AS avg\_tree\_dbh

FROM `bigquery-public-data.new\_york\_trees.tree\_census\_2015`
